HDlive of the Fetal Heart

Toshiyuki Hata, Kenji Kanenishi, Uiko Hanaoka, Hirokazu Tanaka

ABSTRACT

We present the latest HDlive echocardiographic studies on the fetal heart using spatiotemporal image correlation (STIC). Fetal HDlive echocardiography with the use of new skin-like colors provides sonographers and physicians with a natural and anatomically realistic appearance of the fetal heart. Moreover, HDlive images provide entirely new visual experiences for obstetricians and pediatric cardiologists owing to the anatomically realistic depiction of the normal fetal heart and fetal congenital anomalies in utero. This novel technique may assist in the evaluation of the fetal cardiac anatomy, and offer potential advantages relative to conventional two-, three-, and four-dimensional fetal echocardiography. HDlive may be an important modality in future fetal cardiac research and in the evaluation of fetal congenital heart disease.

Keywords: HDlive, Spatiotemporal image correlation, Fetal echocardiography, Surface-rendering mode, Inversion mode, Fetal heart, Normal anatomy, Congenital heart anomaly.

INTRODUCTION

HDlive is a new surface-rendering mode that uses an adjustable light source providing the ability to create lighting and shadowing effects, thereby increasing depth perception.1 HDlive provides such extraordinarily realistic imaging of the embryo and fetus that it is almost impossible to differentiate between actual photographs and ultrasound scans.2,3 There have been several reports, including embryonic, fetal, placental, and umbilical cord HDlive images.4-9 HDlive images obtained using both adjustable lighting and the new skin-like colors also present fetal, placental, and umbilical cord abnormalities with anatomically realistic features similar to those seen in gross specimens.10-18

There have been only two reports on fetal HDlive echocardiographic evaluations of the normal fetal heart and congenital heart anomalies.19,20 HDlive with spatiotemporal image correlation (STIC) provides entirely new visual experiences for obstetricians and pediatric cardiologists owing to the anatomically realistic depiction of normal and abnormal fetal cardiac structures of the beating heart.19 The present paper presents fetal HDlive echocardiographic studies on normal and abnormal fetal cardiac structures, and, based on them, makes recommendations for future research and the application of fetal HDlive echocardiography regarding the antenatal diagnosis of congenital heart anomalies and fetal cardiology research.

SURFACE RENDERING

Normal Heart

Four-chamber View

The dynamic motion of the flap of the foramen ovale was evident (Figs 1 to 2B). Opening and closing of both atrioventricular valves were clearly identified in systole and diastole (see Figs 2A and B). Each papillary muscle was also noted. The orifice of the pulmonary vein was sometimes recognized (see Fig. 2A).

En-face View

Each leaflet of the atrioventricular valves and each cusp of the aortic and pulmonary valves were identified in the
en-face view (Figs 3 to 5B). Opening and closing of the atroventricular, aortic, and pulmonary valves (PVS) were clearly recognized in systole and diastole (see Figs 4A to 5B). Spatial relationships among the four valves were also easily understood in this view.

**Interatrial and Interventricular Septum**

The unique movement of the flap of the foramen ovale (FFO) was evident in systole and diastole (Figs 6A and B). The shape and position of the foramen ovale at the interatrial septum were clearly recognized (Figs 7A and B). The smooth surface of the left interventricular septum was identified (see Fig. 7A), whereas that of the right interventricular septum was slightly rough compared to the left-sided surface (see Fig. 7B).

**Congenital Heart Disease**

**Ventricular Septal Defect**

The shape and position of ventricular septal defect (VSD) were easily understood using HDlive (Figs 8 to 9B). Moreover, the change of shape in systole and diastole was also recognized (see Figs 9A and B).
Figs 5A and B: HDlive images of the en-face view in systole (A) and diastole (B) in a normal fetal heart at 36 weeks and 4 days of gestation (AoV: Aortic valve; MV: Mitral valve; PV: Pulmonary valve; TV: Tricuspid valve)

Tetralogy of Fallot

In the case of tetralogy of fallot (TOF), the overriding aorta and VSD were realistically shown in the four-chamber view (Fig. 10). Moreover, characteristic overriding aortic valve motion was noted using HDlive with STIC in the en-face view (Fig. 11).

Pulmonary Atresia (PA) with VSD

The overriding aorta and a very small pulmonary artery were clearly identified in the en-face view (Fig. 12). VSD was also noted.

Ebstein’s Anomaly

In the case of Ebstein’s anomaly, natural and anatomically realistic appearances of significantly low attachment of the tricuspid valve and the atrialized portion of the right ventricle were shown in the en-face view (Fig. 13). Moreover, elongation of the anterior cusp, shortening of the septal cusp, the atrialized portion of the right ventricle, and the inferior and apical displacement of the tricuspid valve apparatus from its annulus were shown. Thickened leaflets of the tricuspid valve were also noted.

Hypoplastic Left Heart Syndrome

In the case of hypoplastic left heart syndrome (HLHS), a large right ventricle and very small left ventricle with VSD...
were noted in the en-face view (Fig. 14). A very small left ventricle, large right ventricle, and dysplastic pulmonary valve were also clearly shown in systole and diastole in the four-chamber view with the pulmonary artery (Figs 15A and B).

**INVERSION MODE**

The HDlive inversion mode is a very unique and novel technique that provides a means of evaluating fetal cardiac outflow tracts and great vessels. This technique may assist in the evaluation of spatial relationships between the great vessels and both ventricles. It was clearly shown that the pulmonary artery crosses in front of the aorta (Fig. 16). Shunt flow through VSD was also evident (see Fig. 16). The aortic arch and descending aorta were clearly depicted (Figs 16 and 17).

**Fig. 8:** HDlive image of the interatrial and interventricular septum from the left side at 18 weeks and 5 days of gestation. A large ventricular septal defect (VSD) is clearly identified (LV: Left ventricle; PE: Pericardial effusion; RV: Right ventricle)

**Fig. 10:** HDlive image of the four-chamber view of tetralogy of fallot at 35 weeks and 1 day of gestation. An overriding aorta and a ventricular septal defect (VSD) can be noted (AoV: Aortic valve; LV: Left ventricle; MV: Mitral valve; RV: Right ventricle) (Courtesy: Reprinted with permission from Hata T et al)

**Fig. 11:** HDlive image of the en-face view of tetralogy of fallot at 35 weeks and 1 day of gestation. An overriding aortic valve (AoV) is evident (LV: Left ventricle; RV: Right ventricle)
CONCLUSION

This review article focused on HDlive studies on the fetal heart. HDlive provides clinicians with a new and realistic, and arguably much improved, view of the complexities and interrelationships of the fetal cardiac anatomy noninvasively. The influence on fetal cardiology of HDlive in echo technologies might include: (1) the generation of unique information on normal and abnormal intra-cardiac anatomy, (2) evaluation of the fetal heart in the first trimester, and (3) excellent imaging of complex congenital heart disease. The present and future application of this new modality to the prenatal diagnosis of fetuses with congenital heart disease might be promising. However, this is not to imply that HDlive will replace conventional two-, three-, and four-dimensional fetal echocardiography. This novel technique may assist in the prenatal diagnosis of fetal cardiac anomalies, and offer potential advantages relative to conventional two-, three-, and four-dimensional fetal echocardiography and color/power Doppler ultrasound.
